im parsing the status.json file of my Neptune Apex. How do I know if any of the modules or outputs has an error from ...

To identify errors in your Neptune Apex via the `status.json` file, you need to inspect the `hwstat` and `status` fields within the `modules` and `outputs` objects. While Neptune Systems officially recommends `status.xml`, the `status.json` file (found at `/cgi-bin/status.json`) is widely used by developers for its more complete data. Hubitat +1

## 🛠️ Checking Module Health

In the `modules` array, each object represents a connected piece of hardware (e.g., EB832, Trident, FMM).

- **`hwstat` Field**: This is the primary indicator of module health.
  - **"OK"**: The module is communicating correctly.
  - **"Error"** or **"Disconnected"**: The module has lost communication with the base unit.
  - **"Old"**: The module firmware is out of date and should be updated via the Apex local interface.
- **Missing Modules**: If a module you expect to see is entirely missing from the JSON array, it typically indicates a power failure or a severe AquaBus communication break. YouTube +2

---

## 💡 Checking Output Status

Ask anything

- `xstatus` **Field**: For wireless or advanced modules (like Vortech pumps or DOS), this field can contain secondary error codes or specific diagnostic strings. InfluxData

---

## 📊 Identifying Probe Errors

Probes are listed in the `inputs` or `probes` section.

- **Extreme Values**: The Apex doesn't always show a text "error" for probes. Instead, it reports specific "garbage" values:
  - **Temperature**: Extremely high (e.g., 120°F+) or low values often mean the probe is unplugged or the thermistor has failed.
  - **pH/ORP**: If the value is stuck at exactly **0.00** or a maximum like **12.00**, there is likely a hardware fault or the probe is disconnected.

---

## 🔍 Key Paths to Monitor

When parsing the JSON, focus on these paths to build an automated alert system: Neptune Systems Community +1

| Target | JSON Path Example | Error Indicator |
|---|---|---|
| **Modules** | `$.modules[*].hwstat` | Value is not `"OK"` |
| **Outlets** | `$.outputs[*].status` | Value is `"ERR"` |
| **Alarms** | `$.outputs[?(@.name=="EmailAlm")].status` | Value is `"ON"` (indicates a triggered alarm) |
